

Contrasting a ship-based acoustic patch test with an automated calibration routine for a circular-scanning airborne lidar system.

Michael O. Gonsalves, LT/NOAA (NOS/NGS/RSD)
Canadian Hydrographic Conference
22 June 2010

Presentation Overview

- Purpose of study & motivation
- Present calibration practices (sonar & lidar)
- Least-squares approach to lidar
 - Geometric argument
 - Advantages to the least-squares
- Potential application to acoustic multibeam

Purpose of study

To develop a more robust, semi-automated, objective technique for system calibration with reported uncertainties.

The motivation: Why alignment matters

Imagine a downward-looking calibrated laser.

Suppose laser is unknowingly tilted 20° forward.

If operator assumes laser is downward-looking, they will miscalculate the location of the ground.

LIDAR – Why alignment matters

Now suppose there is a target on the ground.

The downward-looking laser correctly identifies the target's location...

...while the forward-looking laser detects the target early, and thus miscalculates the position.

Motivation: why alignment matters

A poorly aligned system leads to:

- Incorrect elevations.
- Miscalculated target positions.
- A general *fuzziness*.

Present calibration practices: Sonar

Two methods – Using general bathymetric trends

Present calibration practices: Sonar

Two methods – Using general bathymetric trends

Present calibration practices: Sonar

Two methods – Using general bathymetric trends

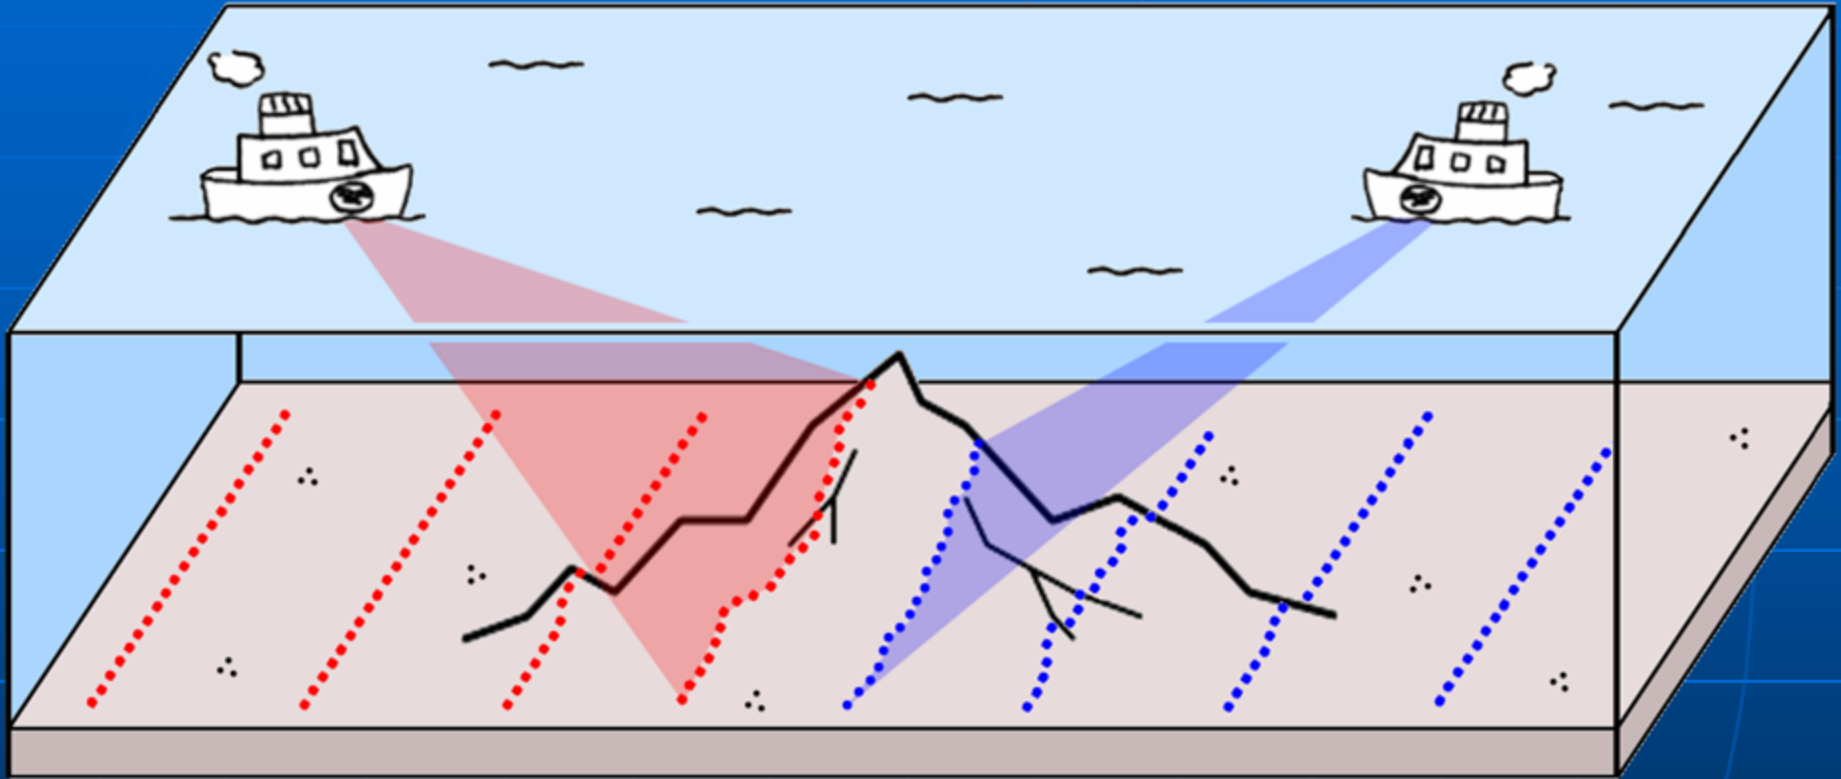

Disadvantages...

- Requires tightly controlled line plan
- Only a limited portion of swath can be used (without risking cross-talk)
- Subject to surveyor's "eye ball"

Present calibration practices: Sonar

Two methods – Using prominent features

Disadvantages...

- Requires locating a suitable feature.
- A small number of pings contribute to solution.
- Assumes co-location of pings on opposing swaths.

Present calibration practices: Lidar

Advantages...

- Can be performed on land
 - No tide or sound velocity concerns
 - Simple to ground-truth

Images courtesy of Optech, Inc. and Google Earth

Present calibration practices: Lidar

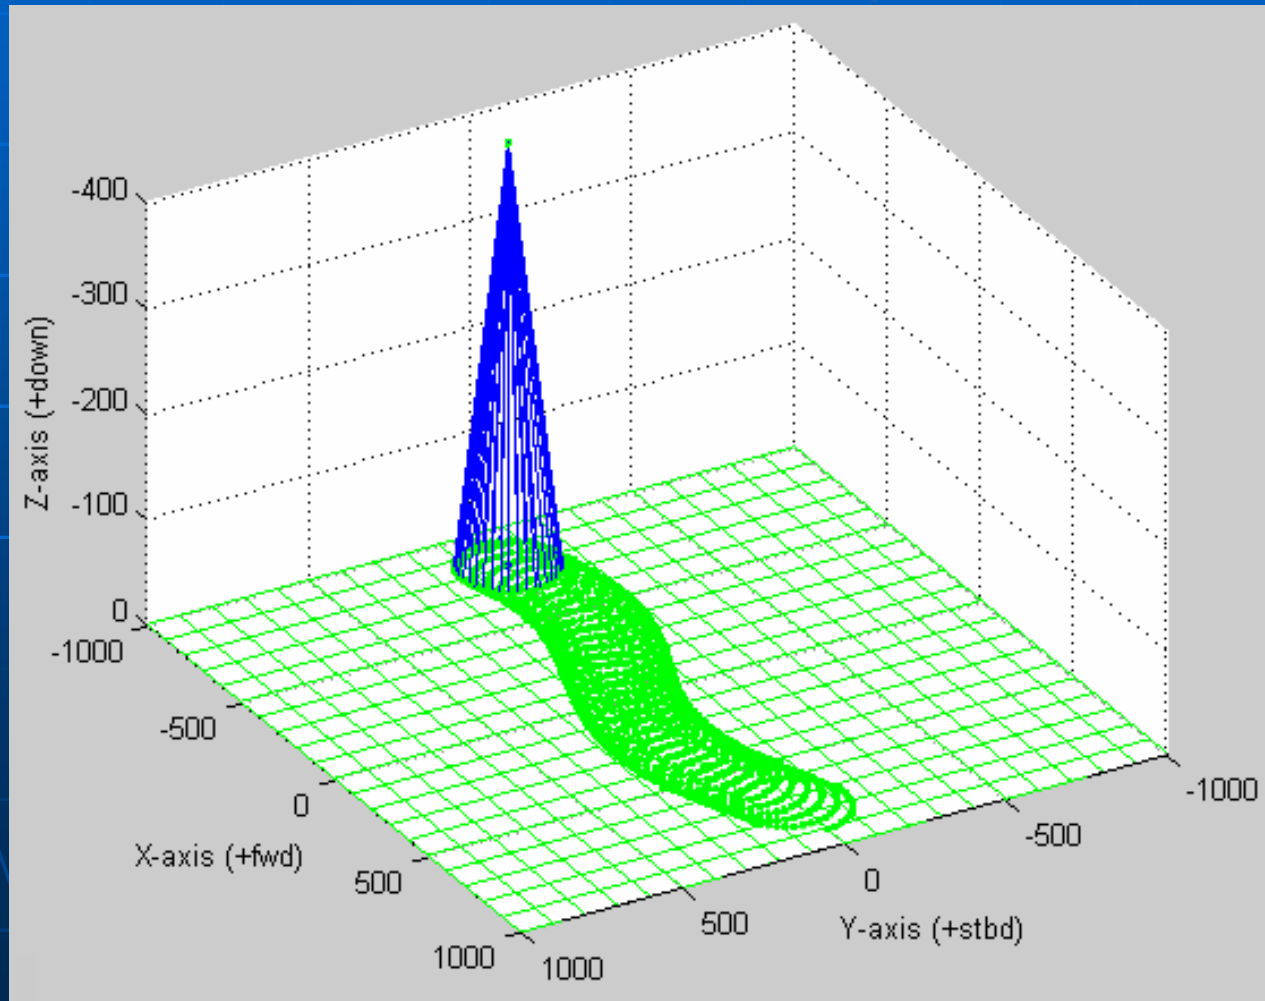

Disdvantages...

- Non-conjugate lidar points (requires adjustment to extracted features)
- Typically requires cultural features

Right image reproduced from Freiss (2006)

A new calibration approach

What if all the data was acquired over and adjusted to a single planar surface, like an airport runway (*or the ocean surface*)?

A weighted least-squares adjustment

Fitting the point cloud to a planar surface.

$$f(\vec{\ell}, \vec{x}) = \vec{n} \cdot (\vec{x}_{OBS} - \vec{x}_p)$$

A weighted least-squares adjustment

The gory details...

A generic function...

$$f(\vec{\ell}, \vec{x}) = 0$$

Has a first-order approximation...

$$f(\vec{\ell}, \vec{x}) \approx \underbrace{f(\vec{\ell}_0, \vec{x}_0)}_{\vec{g}} + \underbrace{(\vec{\ell} - \vec{\ell}_0)}_{\vec{r}} \underbrace{\frac{\partial f}{\partial \ell} \Big|_{\vec{\ell}=\vec{\ell}_0, \vec{x}=\vec{x}_0}}_{\mathbf{D}} + \underbrace{(\vec{x} - \vec{x}_0)}_{\vec{\delta}} \underbrace{\frac{\partial f}{\partial x} \Big|_{\vec{\ell}=\vec{\ell}_0, \vec{x}=\vec{x}_0}}_{\mathbf{A}} \approx 0$$

$$f(\vec{\ell}, \vec{x}) \approx \vec{g} + \mathbf{D}\vec{r} + \mathbf{A}\vec{\delta} \approx 0$$

Which has an iterative approximation for \vec{x} of...

$$\vec{\delta} = \left(\mathbf{C}_{x_0}^{-1} + \mathbf{A}^T \left(\mathbf{D} \mathbf{C}_\ell \mathbf{D}^T \right)^{-1} \mathbf{A} \right)^{-1} \mathbf{A}^T \left(\mathbf{D} \mathbf{C}_\ell \mathbf{D}^T \right) \vec{g}$$

A geometric argument

Sensor reference frame to INS reference frame

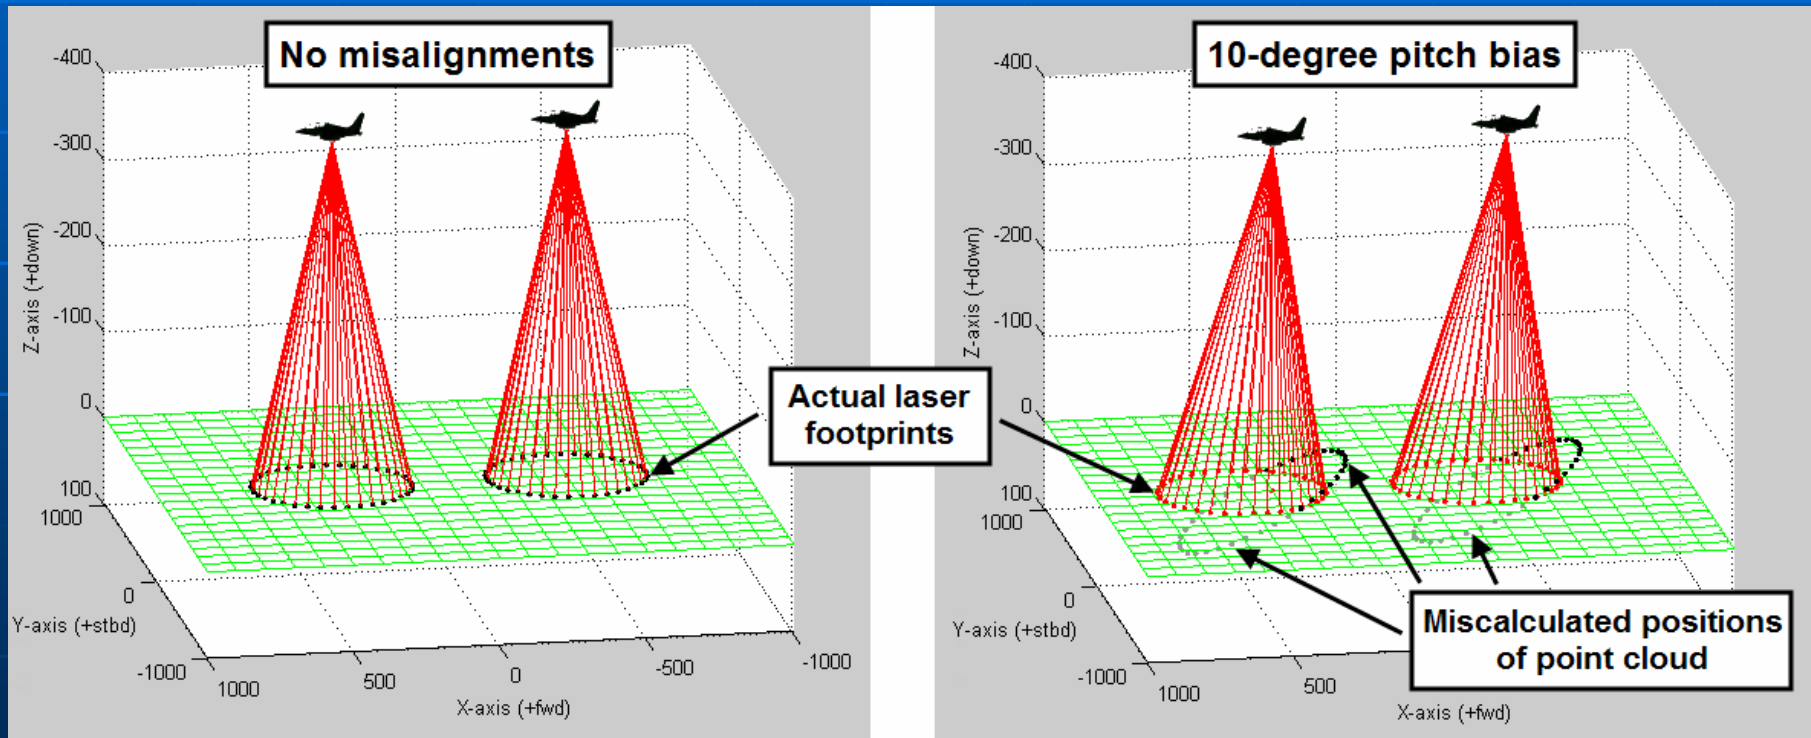

- Lidar = boresight misalignments
- Sonar = patch test values

A geometric argument

Fitting the data to a planar surface

- Data is initially acquired over a flat surface
- Adjustment procedure is then designed to fit data to a planar surface.

Pitch!

A geometric argument

- A single, straight flight line will not yield enough information to extract the roll boresight misalignment.
- The popular approach is to fly opposing flight lines, *although...*

Roll!

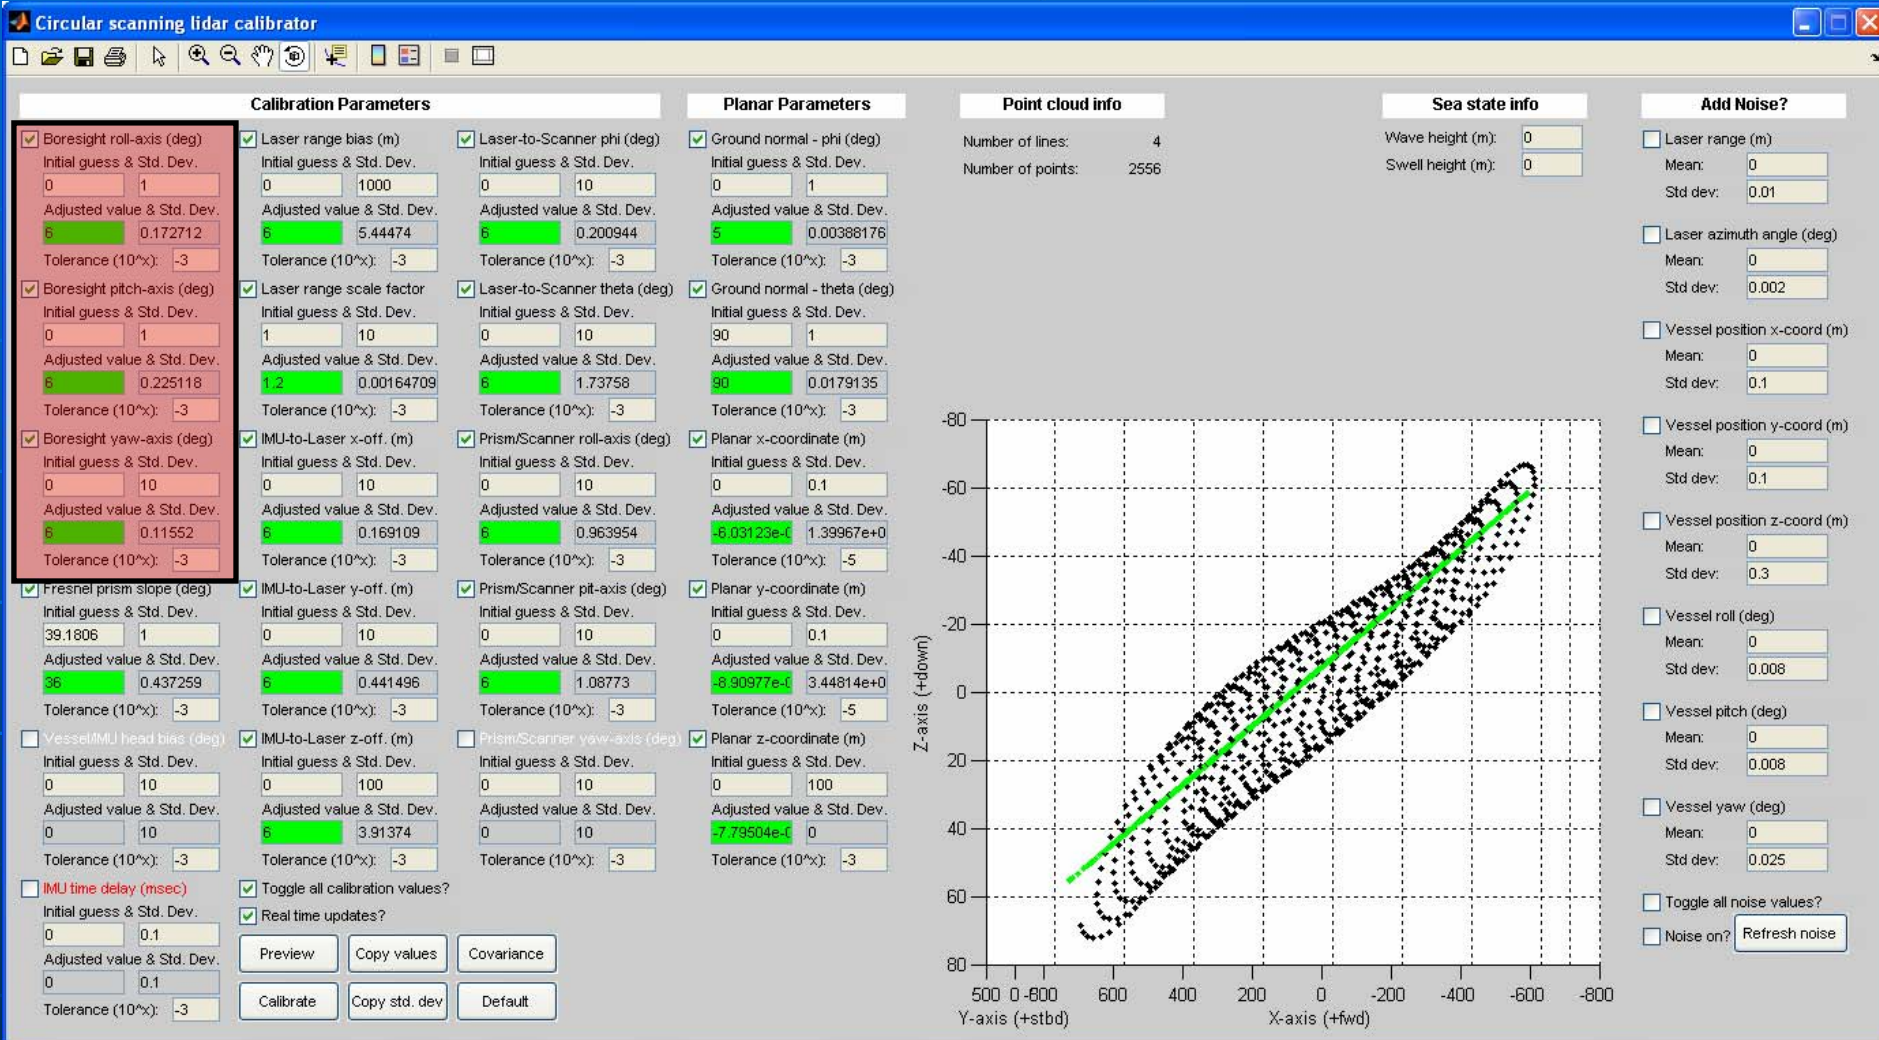

A geometric argument

- Even heading boresight misalignments can be determined from a flat featureless surface – provided the vessel surveys with ~attitude~ (not altitudes)

Yaw!

The Geometric Calibrator

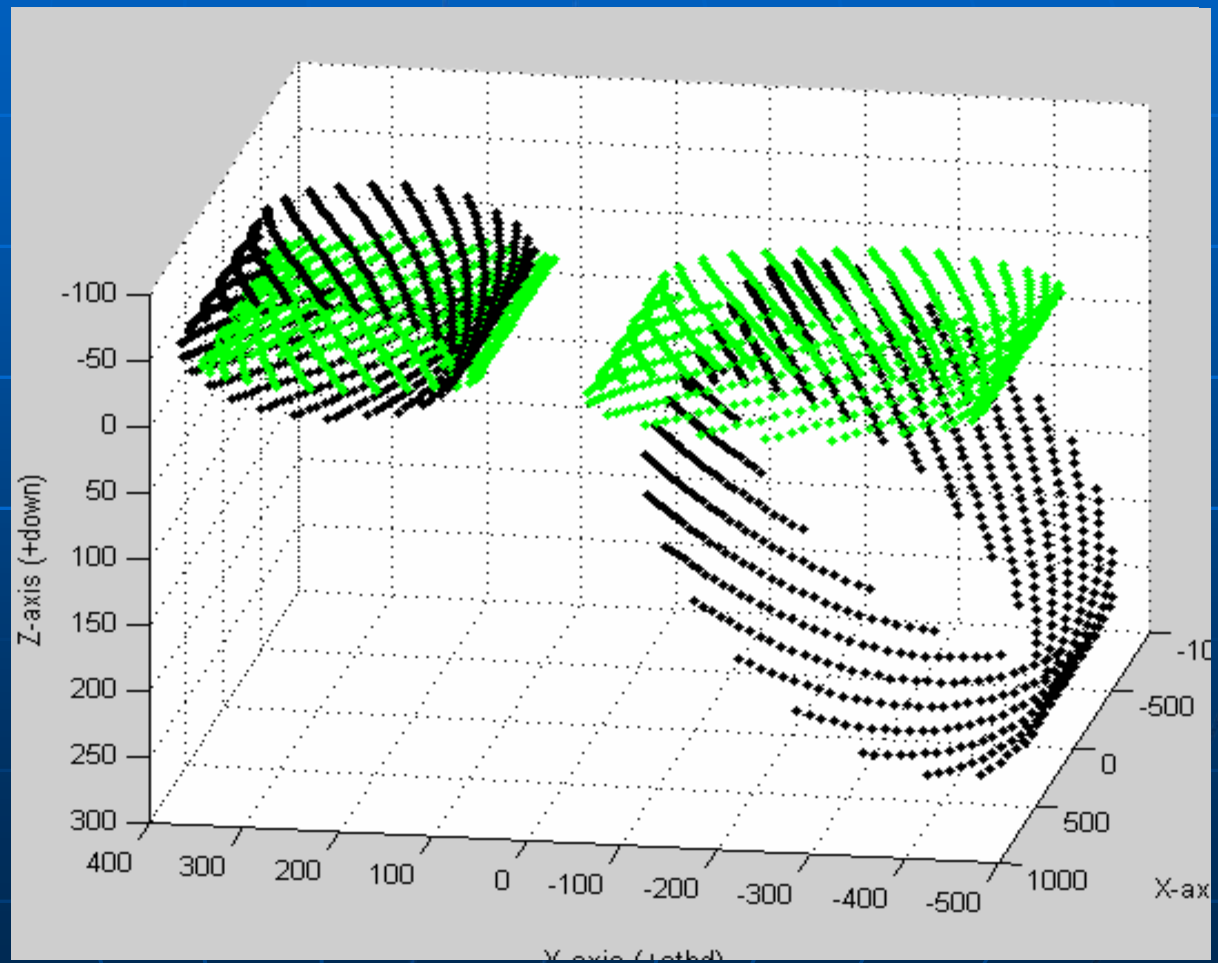

The calibrator in action

- Misalignments: 10° roll, 20° pitch, 30° yaw biases
- Flight plan: Two lines – opposite heading (0° & 180°) and opposite attitude ($\pm 20^\circ$ pitch)

☒ Boresight roll-axis (deg)
Initial guess & Std. Dev.
0 1
Adjusted value & Std. Dev.
10 0.003816
Tolerance (10^x): -3

☒ Boresight pitch-axis (deg)
Initial guess & Std. Dev.
0 1
Adjusted value & Std. Dev.
20 0.00302905
Tolerance (10^x): -3

☒ Boresight yaw-axis (deg)
Initial guess & Std. Dev.
0 10
Adjusted value & Std. Dev.
30 0.0129071
Tolerance (10^x): -3

Also works with noisy data

- Anticipated sensor noise added to all observations

☒ Boresight roll-axis (deg)
Initial guess & Std. Dev.
0 1
Adjusted value & Std. Dev.
10.0036 0.00381606
Tolerance (10^x): -3

☒ Boresight pitch-axis (deg)
Initial guess & Std. Dev.
0 1
Adjusted value & Std. Dev.
19.9978 0.00302911
Tolerance (10^x): -3

☒ Boresight yaw-axis (deg)
Initial guess & Std. Dev.
0 10
Adjusted value & Std. Dev.
29.9939 0.0129079
Tolerance (10^x): -3

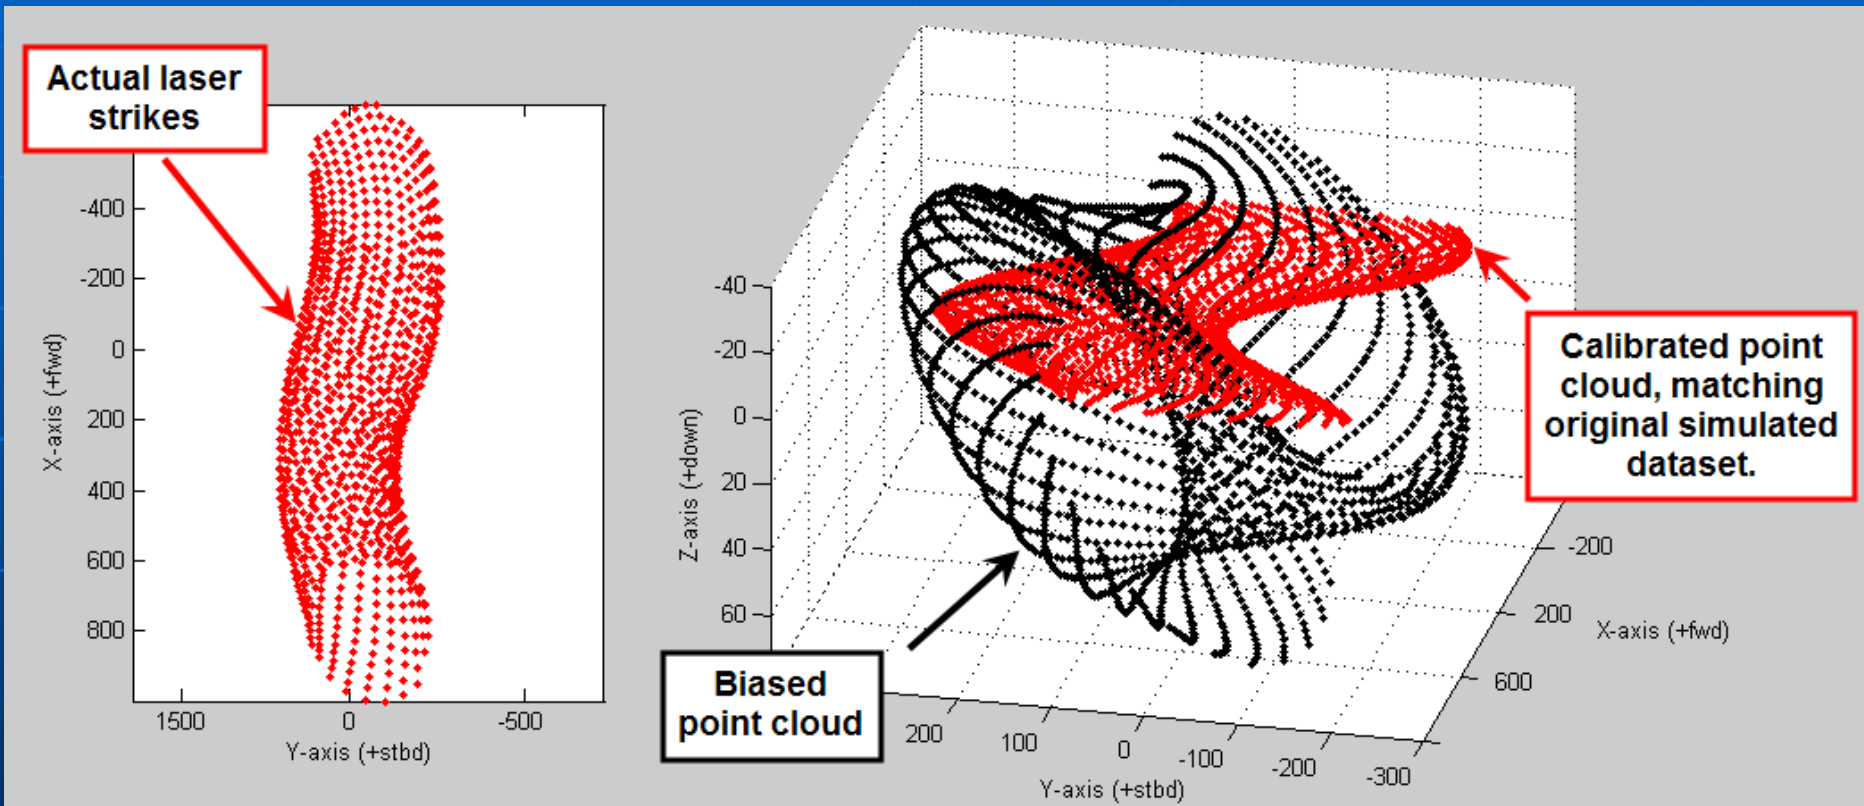

Measurement noise (1-sigma) for various system components

Laser range (m)	0.01
Laser azimuth (deg)	0.002°
GPS x-position (m)	0.10
GPS y-position (m)	0.10
GPS z-position (m)	0.30
Vessel roll (deg)	0.008°
Vessel pitch (deg)	0.008°
Vessel yaw (deg)	0.025°

Uncertainty estimates from
POS AV 410 (with post processing)

Calibration of a single wiggly flight line

- Rather than flying multiple directions, the roll bias can be determined provided the aircraft just changes heading.

- The greater the change, the better the results and more confident the reported uncertainty.

There's more than just boresight...

There's more than just boresight...

- 4 flight lines (36K points)
- Rolling, Yawing, Pitching, Heaving
- 12 calibration parameters

Replay at 20x normal speed

There's more than just boresight...

- 4 flight lines (36K points)
- Rolling, Yawing, Pitching, Heaving
- 12 calibration parameters

Advantages to a weighted least-squares adjustment model

- Simultaneous adjustment of several parameters from a *single* dynamic flight line (yet flexible in number of parameters pursued)
- Produces uncertainty estimates for calibration parameters (used to initialize a TPU model)
- Automated, objective method
- Covariance matrix shows correlation among parameters
- Examination of residuals can identify fliers
- Potential *real-time* calibration (no longer separating calibration lines and acquisition lines).
- Potential *background* calibration (system warns operator when a misalignment is detected)
